

# NCP81391, NCP81391A

## Advance Information Integrated Driver and MOSFET

The NCP81391/A integrates a MOSFET driver, high-side MOSFET and low-side MOSFET into a single package. The driver and MOSFETs have been optimized for high-current DC-DC buck-boost power conversion applications. The NCP81391/A integrated solution greatly reduces package parasitics and board space compared to a discrete component solution.

### Features

- Capable of Average Currents up to 25 A
- Capable of Peak Currents up to 65 A
- Over 97% Peak-Efficiency
- Compatible with 3.3 V and 5 V PWM Inputs, with Tri-State
- Zero Current Detection for Improving Light Load Efficiency
- Optional Thermal Shutdown Protection
  - ◆ NCP81391: With Thermal Shutdown
  - ◆ NCP81391A: No Thermal Shutdown
- Internal Bootstrap Diode
- Undervoltage Lockout
- This is a Pb-Free Device

### Applications

- E-Cigarettes
- Unmanned Aerial Vehicles

## NCP81391, NCP81391A

**Figure 2. Simplified Block Diagram**

**Table 1. PIN LIST AND DESCRIPTIONS**

Pin No.	Symbol	Description
1	PHASE	Bootstrap Capacitor Return
2	PGND2	Power Ground
3	CGND	Signal Ground
4	EN	Enable. There is a pull-down resistor to CGND for the NCP81391. No pull-down resistor for NCP81391A.
5	PWM	PWM Control Input: PWM = High → HS FET is on, LS FET is off PWM = Mid → HS FET is off, LS FET is off PWM = Low, ZCD_EN# = High → HS FET is off, LS FET is on PWM = Low, ZCD_EN# = Low → HS FET is off, LS FET is off when zero current is detected
6	ZCD_EN#	Zero Current Detect Control. When this pin is at logic low, low-side FET will turn off when zero inductor current is detected (after a minimum blanking/de-bounce time). There is an internal pull-up resistor.
7	VCC	Control Power Supply Input
8	VCCD	Driver Power Supply Input
9	NC9	No Connect
10	BST	Bootstrap Supply Voltage. Connect a MLCC capacitor of at least 0.1 μF from this pin to PHASE.
11	GH	High-Side MOSFET Gate Access. Leave floating.
12	NC12	No Connect
13	VIN13	Conversion Supply Power Input
14	VIN14	Conversion Supply Power Input
15	VIN15	Conversion Supply Power Input

## APPLICATIONS INFORMATION

### Theory of Operation

#### Low-Side Driver

The low-side driver drives a ground-referenced low- $R_{DS(on)}$  N-Channel MOSFET. The voltage rail for the low-side driver is internally connected to VCCD and CGND.

The GLD pin connects directly to the output of the low-side driver. The GLF pins connects directly to the gate of the low-side MOSFET. See Figure 2. GLD and GLF are not connected inside the package. For proper operation, these pins must be connected together on the PCB.

#### High-Side Driver

The high-side driver drives a floating low- $R_{DS(on)}$  N-channel MOSFET. The gate voltage for the high-side driver is developed by a bootstrap circuit referenced to the PHASE pin, which is internally connected to the VSWH pin.

The bootstrap circuit is comprised of an internal diode and an external bootstrap capacitor. When the NCP81391/A is starting up, the VSWH pin is at ground, so the bootstrap capacitor charges up to VCCD through the bootstrap diode (see Figure 1). When the PWM input goes high, the high-side driver will begin to turn on the high-side MOSFET using the stored charge of the bootstrap capacitor. As the high-side MOSFET turns on, the voltage at the VSWH pin rises. When the high-side MOSFET is fully on, the VSWH voltage equals the VIN voltage, with the BST voltage higher than VIN by the amount of voltage on the bootstrap capacitor. The bootstrap capacitor is recharged when the switch node goes low during the next cycle.

Parasitic inductances and capacitances within the packaging and MOSFETs can cause significant ringing of the VSWH signal during turn-on and turn-off of the high-side MOSFET. When operating at high input voltages and high output currents, the peak ringing voltages on VSWH could cause the drain-to-source voltage across the MOSFETs to exceed its maximum rating. Including a resistor in series with the bootstrap capacitor can reduce the peak VSWH ringing voltages. A resistor value of 4  $\Omega$  is recommended when operating at VIN voltages greater than 16 V.

#### Overlap Protection Circuit

As PWM transitions between the logic high and logic low states, the driver circuitry prevents both MOSFETs from being on at the same time. While one MOSFET is turned off, the driver monitors the gate voltage of that MOSFET until it reaches 1 V. At this point, a non-overlap timer is started, and prevents the gate of the other MOSFET from going high until this timer expires. In the electrical characteristics table, this non-overlap timer is specified as the time between 1 V of the falling gate and 10% of the high value of the rising gate.

#### Three-State PWM Input

Switching PWM between logic-high and logic-low states allows the driver to operate in continuous conduction mode, as long as VCC is greater than the UVLO threshold and EN is high.

The PWM mid-state allows the NCP81391/A to enter a high-impedance mode, where both MOSFETs are off.

**Table 6. EN/PWM LOGIC TABLE**

EN	PWM	ZCD_EN#	GH	GL
LOW	X	X	LOW	LOW
HIGH	LOW	HIGH	LOW	HIGH
HIGH	MID	HIGH	LOW	LOW
HIGH	HIGH	HIGH	HIGH	LOW
HIGH	LOW	LOW	LOW	ZCD
HIGH	MID	LOW	LOW	LOW
HIGH	HIGH	LOW	HIGH	LOW

#### Zero Current Detection

At light load conditions, the inductor current can be negative due to the inductor current ripple. The zero current detection (ZCD) function in the NCP81391/A can prevent negative current during these light load conditions. When ZCD is active, the NCP81391/A will monitor the voltage at the VSWH pins when the LS FET is on and conducting. There is a blanking/de-bounce timer that delays when this monitoring starts, from the time GL goes high. As the inductor current falls towards zero, the voltage on VSWH will become less negative. When the VSWH voltage reaches the ZCD threshold, the LS FET is turned off. Positive current can still flow through the body diode of the LS FET, but the body diode will block any current in the negative direction.

ZCD is activated by placing ZCD\_EN# in the logic-low state. There is an internal pull-up resistor at the ZCD\_EN# pin.

Whenever VCC rises above the UVLO threshold, an auto-calibration is conducted on the ZCD Threshold. During the auto-calibration, the driver outputs will remain low and not respond to the PWM input. The auto-calibration cycle takes 28  $\mu$ s to complete, typically.

#### Thermal Shutdown

With the NCP81391, if the driver temperature exceeds  $T_{THDN}$ , the part will enter thermal shutdown and turn off both MOSFETs. After the temperature decreases to  $T_{THDN} - T_{THDN\_HYS}$ , the part will resume normal operation.

For applications that prefer not to have this power stage have a thermal shutdown, the NCP81391A removes the thermal shutdown protection feature.

To distinguish between the NCP81391 and NCP81391A, externally, the NCP81391 has an internal pull-down resistor at the EN pin while the NCP81391A does not have an internal pull-down resistor at the EN pin.

## NCP81391, NCP81391A

### Power Supply Decoupling

The NCP81391/A sources relatively large currents into the MOSFET gates. In order to maintain a constant and stable input supply voltage, low-ESR capacitors should be placed between VCC and GND and between VCCD and ground, close to the NCP81391/A. A 1  $\mu$ F to 4.7  $\mu$ F multilayer ceramic capacitor (MLCC) is sufficient. To further filter noise from VCCD from entering the VCC pin, placing a 10  $\Omega$  resistor between the VCC and VCCD pins is recommended.

### Bootstrap Circuit

The bootstrap circuit uses an external charge storage capacitor ( $C_{BST}$ ) and the internal bootstrap diode. The bootstrap capacitor should have a voltage rating twice the maximum VCCD supply voltage. A bootstrap capacitance of at least 100 nF with a minimum 25 V rating is recommended. For best performances, use a 1  $\mu$ F ceramic capacitor.

In order to prevent the bootstrap capacitor from discharging during conditions where the high side is turned on for a long time, such as high duty cycle or ZCD, a

maximum duty cycle must be respected. The maximum duty cycle depends on the two time constants that appear during the charging time (converter's  $t_{off}$ ) and discharging time (converter's  $t_{on}$ ). To keep the bootstrap capacitor charged, the following relation must kept.

$$D \cdot \frac{R_{drv}}{(1 - D) \cdot R_{bst}} > 50$$

Thus,  $D_{max}$  can be expressed as

$$D_{max} = 1 - \frac{R_{bst}}{\frac{R_{drv}}{50} + R_{bst}}$$

With the converter's duty cycle,  $R_{drv}$  the High-Side Driver equivalent resistance from VBST to VSWH (typically 5 k $\Omega$ ),  $R_{bst}$  the bootstrap series resistor. Note that the bootstrap capacitance has no effect on maximum duty cycle since it is common in both time constants.

Example:

$f_{sw} = 250$  kHz,  $R_{drv} = 5$  k $\Omega$ ,  $R_{bst} = 4$   $\Omega$ , the maximum duty cycle allowed to keep the bootstrap capacitor charged is  $D_{max} = 96\%$  and  $t_{on\_max} = D_{max}/f_{sw} = 3.84$   $\mu$ s.
